## Purpose and audience

The purpose of the Health GeoLab Collaborative guidance is to inform concerned practitioners about the key elements they need to be aware of when it comes to managing and using geospatial data and technologies in public health and guide them through the processes to be followed in that regard.

The audience for this guidance includes managers, technical advisors, enumerators, and any other practitioners that are directly or indirectly involved in the collection and use of geospatial data in health.

Please note that some of the sections in this guide require a basic understanding of concepts pertaining to the management and use of geospatial data and technologies.

## Abbreviations

ADB	Asian Development Bank
AeHIN	Asia eHealth Information Network
DEM	Digital Elevation Model
GIS	Geographic Information System
HGLC	Health GeoLab Collaborative
HIS	Health Information System
MORU	Mahidol-Oxford Tropical Medicine Research Unit
SDG	Sustainable Development Goal
WHO	World Health Organization

# 1. Background

The Health GeoLab Collaborative (HGLC) is a collective of institutions and individuals sharing the same vision - for low- and middle-income countries in Asia and the Pacific to fully benefit from the power of geography, geospatial data, and technologies to reach the health-related Sustainable Development Goal of healthy lives and well-being for all (SDG 3)<sup>1</sup>.

The HGLC uses the 4Ts (Training, Tooling, Testing, and Teaming) approach to strengthen in-country capacity. The present guidance has been developed as part of this approach and with the objective to be used by the largest number of users possible.

This guidance is part of a series started under the umbrella of the AeHIN GIS Lab and now continued by the HGLC. The complete series of the guidance is organized as follows:

- Part 1 - Introduction to the data-information-knowledge-decision continuum and the geospatial data management cycle [1]
- Part 2 - Implementing the geospatial data management cycle:
  - 2.1 Documenting the process and defining the data needs [2]
  - 2.2 Defining the vocabulary, the data set specifications, and the ground reference [3]
  - 2.3 Compiling existing data and identifying gaps (the present document)
  - 2.4 Creating geospatial data
    - 2.4.1 Extracting data from other sources [4]
    - 2.4.2 Collecting data in the field [5]
  - 2.5 Cleaning, validating, and documenting the data
    - 2.5.1 Documenting the data using a Metadata profile [6]
  - 2.6 Distributing, using, and updating the data.
    - 2.6.1 Creating good thematic maps using desktop GIS software [7]

This guidance is a living document made to evolve based on the inputs received from the users. Please don't hesitate to contact us at [info@healthgeolab.net](mailto:info@healthgeolab.net) if you have any suggestions for improvement.

Please also contact us using the same email address should you use this document as part of your activities and would like to have your institution recognized as one of the document's users.

## 2. Introduction

Once the data needs have been identified [2] and before collecting new data in the field, it is advisable to compile the data already available and see if it is appropriate for the initial purpose and that it complies with the data specifications and ground reference that have been pre-defined [3]. This process prevents duplication of efforts, saves time and money, and allows identification of potential gaps.

The present document's objective is to guide users through the above mentioned process. While this process is to be applied to both geospatial and statistical data, the present guide focuses mainly on the former.

The definition for the technical terms used in this guidance can be found in the following Google Sheet: <https://bit.ly/2q27s0l>.

### 3. Compiling existing datasets

The compilation process needs to cover the following in order to lead to a quality dataset:

1. The master list for the geographic features considered in the data model [2]
2. The thematic layers containing the geospatial representation (geographic objects) for the considered geographic features
3. The statistical data to be attached to these features
4. Basemaps to serve as ground reference when checking the geospatial data that has been collected

While master lists should only come from the governmental entity having the official mandate over the considered geographic feature(s), geospatial and statistical data as well as basemaps can themselves come from different sources depending on the needs identified at the beginning of the process and their availability. It is therefore important to consider all of these sources as they might be complementary and under different use and redistribution rights constraints.

Table 1 gives the list of the governmental entities generally in charge of the master list and associated thematic layer for the geographic features most often used in public health.

Geographic feature	Master list	Thematic layer	Governmental entity
Health facilities	✓	✓	Ministry of Health, NGO (WHO)
Health districts or other reporting divisions	✓	✓	Ministry of Health, NGO (WHO)
Administrative divisions and villages	✓	✓	Ministry of Interior, National Statistical Agency, National Mapping Agency
Transportation network	Not necessary	✓	Ministry of Public Works, Ministry of Transportation
Hydrographic network	Not necessary	✓	Ministry of Environment/Agriculture
Climate data (temperature, precipitation, etc.)	Not applicable	✓	Ministry of Meteorology, Meteorological agency
Digital Elevation Model (DEM)	Not applicable	✓	National Mapping Agency
Land cover	Not applicable	✓	National Mapping Agency, Ministry of Environment/Agriculture

Table 1. Governmental entities having the mandate over the geographic features mainly used in public health

The other potential sources of local, regional or global geospatial and statistical data can be non-government organizations (NGOs), volunteer/community groups, research groups, universities, and the private sector. When accessible, much of this data can be downloaded directly from the internet, with some requiring registration with the institution that distributes the data.

Basemaps are accessible either through the GIS software you are using or through online web mapping services such as ArcGIS Online or Google Maps.

Whatever the source of the data being compiled, it is always very important to collect the metadata associated with it [6]. If such metadata is not directly attached to the data file itself, this should be collected separately and kept together with it (e.g., in the same folder).

At minimum, the metadata should include the following in order to be useful:

1. What is the data about?
2. Who created the data?
3. When was the data created/collected/last updated?
4. How was the data created?
5. What are the data specifications (geographic coordinate system/projection system, scale, accuracy, language..)?
6. Are there any use or redistribution restrictions attached to the data?
7. Who can I contact if I have questions about the data?

## 4. Organizing the compiled data

As you are compiling the data, it is important to organize it on your computer in such a way that it is easy to find, including by other people. The filing structure should change as little as possible to avoid losing the path to these datasets once they are stored in a project file (.mxd, .qgs) generated from a GIS software. Figure 1 provides an example of a folder organization structure.

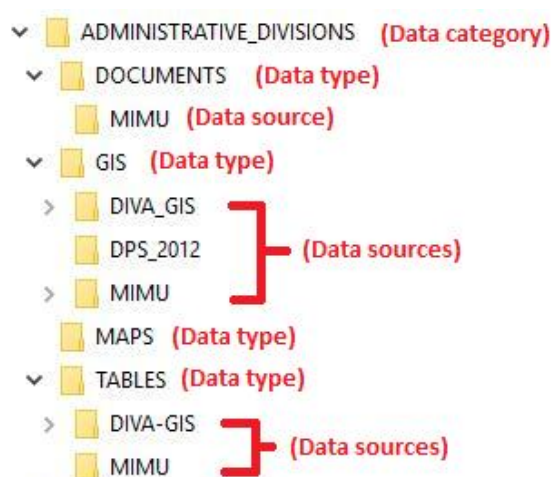

Figure 1. Example of folder organization structure

In the folder organization structure shown in Figure 1, files are organized by:

1. **Data category** corresponding to the different geographic features being collected (health facilities, administrative divisions, Digital Elevation Model (DEM), etc.)
2. **Data type**. Four main types are generally considered:
  - a. DOCUMENTS: for reports, publications and other narrative documents
  - b. GIS: for thematic layers saved in a GIS-compatible format (shapefile, GeoJSON, etc.)
  - c. MAPS: for maps saved in pdf, Microsoft Word format or images (.jpg, .bmp, .png, etc.)
  - d. TABLES: for any data saved in a tabular format (Microsoft Excel, CSV, etc.)
3. **Data source** with one folder for each source, the corresponding data being saved in each of these folders. Please note that the year of data production is included together with the data source in the folder name when known (e.g., DPS\_2012).

## 5. Assessing the compiled data and documenting the gaps

Once all the available data is compiled and organized, it is important to assess it in order to identify:

- If you have been able to find at least one source for each of the data needed at the beginning of the process [2]
- Which source(s) are of best quality according to the six (6) dimensions documented in the data specifications (timeliness, uniqueness, completeness, validity, accuracy, and consistency) and the use of the defined ground references [3]

While the first part of the assessment is straightforward and consists only of making a list of data that has not been possible to find, the second part requires a more in-depth analysis.

Annex 1 has been developed to help conduct this second part of the assessment based on the data type (geospatial i.e., vector or raster format, or statistical). This assessment takes the form of questions applied to each available source and for which the answer is simply 'Yes' or 'No'.

Please note that the ability to answer these questions very much depends on the availability of data specifications and ground references (master lists and satellite images) being defined and identified prior to the data compilation exercise [3]. Without these, only a limited number of data quality dimensions can be assessed, making the choice of the source with the highest quality more difficult.

While the sources with the highest number of 'Yes' are most likely to be the most appropriate for the project, there is no perfect rule in this regard and the amount of work to fill the potential remaining gaps will have to be taken into account when taking this decision. For example:

- Temporal discrepancies (Criteria 1 and 2 in Annex 1): Such discrepancies between datasets are a common issue that can have a big impact on the results and might require a lot of work to be addressed. Comparing the location of health facilities as observed today with the road network as it was in place 10 years ago is one example.
- The lack of documentation (metadata) might not only lead to technical issues such as the impossibility to correctly project a geospatial dataset or the use of data that was actually not meant to be shared in the first place but using data without knowing its use and redistribution rights might end up being more problematic than using other sources of lower quality but for which these information are known.
- The gaps in authoritative data from the government might be too big compared to other sources for them to be considered

It is possible that, at the end of the assessment, none of the data that has been compiled presents a quality sufficient enough to justify their use. The following options should be considered in this case:

- Look for additional sources that might have been missed during the first round of data compilation;
- Identify if combining different sources of data together could help cover the gap(s);

If none of the above is possible then remaining data gaps should be documented and properly mentioned not only in the metadata profile but also on any maps that would be created using this data.

The next natural step in the process, when possible, would consist of extracting data from other sources [4] or collecting data in the field [5].

## Annex 1 - Criteria for the assessing the compiled data across the 6 dimensions of data quality

	Timeliness	Uniqueness	Completeness	Validity		Accuracy		Consistency		
Geospatial data (vector format)	1. The geospatial data has been created, or updated for the last time, during the period defined in the data specifications?	3. The geospatial data does not contain any duplicates that could impact the completeness assessment?	5. The geospatial data contains all the records reported in the master list for the time period considered for the project?	8. A metadata profile is available for the geospatial data and contains all the information necessary for its use, starting with the geographic and projected coordinate systems as well as the use and redistribution rights?	NA	11. The geospatial data is available in a format that allows its use in the GIS software selected for the project or could be converted in such format?	13. The scale at which the geospatial data has been created is compatible with the one defined in the data specifications?	15. The geographic objects in the geospatial data are located within the accuracy measure defined in the data specifications on the satellite images used as the ground reference?	17. The geospatial or statistical data is coming from the governmentnal entity in charge of it?	17. The geospatial datas presenting the highest quality based on the other dimensions are consistent among each other in terms of timeliness and accuracy
Geospatial data (raster format)		NA	NA		10. The geospatial data covers the all study area as defined for the project?		14. The resolution of the geospatial data is compatible with the one defined in the data specifications?	16. The recognizable features in the geospatial data (coastline for example) are aligned with their corresponding feature on the satellite images used as the ground reference?		
Statistical data (tabular)	2. The statistical data has been collected during the period defined in the data specifications?	4. The statistical data does not contain any duplicates?	7. A value is available for each of the records contained in the master list for the corresponding feature?	9. A metadata profile is available for the statistical data and contains all the information necessary for its use?		12. The statistical data is available in a format that allows its use in the context of the project or could be converted in such format?	NA			NA
